**Abstract.** In this paper, we propose a new algorithm for computing recursive closures. The main idea behind this is tree labeling and graph decomposition, based on which the transitive closure of a directed graph can be computed in  $O(e \cdot b)$  time and  $O(n \cdot b)$  space, where  $n$  is the number of the nodes of the graph,  $e$  is the numbers of the edges, and  $b$  is the graph's breadth. It is a better computational complexity than any existing algorithms for this problem.

## 1. Introduction

Let  $G = (V, E)$  be a directed graph (*digraph* for short). Digraph  $G^* = (V, E^*)$  is the reflexive, transitive closure of  $G$  if  $(v, w) \in E^*$  iff there is a path from  $v$  to  $w$  in  $G$ . In this paper, we present a new algorithm for computing the transitive closure of a digraph efficiently.

## 2. Tree labeling

In this section, we mainly discuss the concepts of tree labeling and graph decomposition, based on which our algorithm is designed. For any directed tree  $T$ , we can label it as follows. By traversing  $T$  in *preorder*, each node  $v$  will obtain a number  $pre(v)$  to record the order in which the nodes of the tree are visited. In a similar way, by traversing  $T$  in *postorder*, each node  $v$  will get another number  $post(v)$ . These two numbers can be used to characterize the ancestor-descendant relationships of nodes as follows.

**Proposition 1.** Let  $v$  and  $v'$  be two nodes of a tree  $T$ . Then,  $v'$  is a descendant of  $v$  iff  $pre(v') > pre(v)$  and  $post(v') < post(v)$ .

*Proof.* See [Kn73]. □

If  $v'$  is a descendant of  $v$ , then we know that  $pre(v') > pre(v)$  according to the preorder search. Now we assume that  $post(v') > post(v)$ . Then, according to the postorder search, either  $v'$  is in some subtree on the right side of  $v$ , or  $v$  is in the subtree rooted at  $v'$ , which contradicts the fact that  $v'$  is a descendant of  $v$ . Therefore,  $post(v')$  must be less than  $post(v)$ .

The following example helps for illustration.

**Example 1.** See the pairs associated with the nodes of the directed tree shown in Fig. 1. The first element of each pair is the preorder number of the corresponding node and the second is its postorder number. Using such labels, the ancestor-descendant relationships of nodes can be easily checked. For instance, by checking the label associated with  $b$  against the label for  $f$ , we know that  $b$  is an ancestor of  $f$  in terms of Proposition 1. We can also see that since the pairs associated with  $g$  and  $c$  do not satisfy the condition given in Proposition 1,  $g$  must not be an ancestor of  $c$  and *vice versa*.

Let  $(p, q)$  and  $(p', q')$  be two pairs associated with nodes  $u$  and  $v$ . We say that  $(p, q)$  is subsumed by  $(p', q')$ , denoted  $(p, q) \prec (p', q')$ , if  $p > p'$  and  $q < q'$ . Then,  $u$  is a descendant of  $v$  if  $(p, q)$  is subsumed by  $(p', q')$ .

## 3. Branchings and graph decomposition

Now we discuss how to recognize the ancestor-descendant relationships w.r.t. a general structure: a DAG or a graph containing cycles. First, we address the problem of DAGs in 3.1. Then, cyclic graphs will be discussed in 3.2.

### 3.1 Recursion w.r.t. DAGs

What we want is to apply the technique discussed above to a DAG. To this end, we establish a *branching* of the DAG as follows.

**Definition 2.** (*branching* [Ta77]) A subgraph  $B = (V, E')$  of a digraph  $G = (V, E)$  is called a branching if it is cycle-free and  $d_{indegree}(v) \leq 1$  for every  $v \in V$ .

Clearly, if for only one node  $r$ ,  $d_{indegree}(r) = 0$ , and for all the rest of the nodes,  $v$ ,  $d_{indegree}(v) = 1$ , then the branching is a directed tree with root  $r$ . Normally, a branching is a set of directed trees. Now, we assign each edge  $e$  a same cost (e.g., let  $cost\ c(e) = 1$  for every edge). We will find a branching for which the sum of the edge costs,  $\sum c(e)$ , is maximum.

Fig. 1. Labeling a tree

Fig. 2. A DAG and its branching

For example, the trees shown in Fig. 2(b) are a maximal branching of the graph shown in Fig. 2(a) if each edge has a same cost.

Assume that the maximal branching for  $G = (V, E)$  is a set of trees  $T_i$  with root  $r_i$  ( $i = 1, \dots, m$ ). We introduce a *virtual root*  $r$  for the branching and an edge  $r \rightarrow r_i$  for each  $T_i$ , obtaining a tree  $G_r$  called the representation of  $G$ . For instance, the tree shown in Fig. 2(c) is the representation of the graph shown in Fig. 2(a). Using Tarjan's algorithm for finding optimum branchings [Ta77], we can always find a maximal branching for a directed graph in  $O(|E|)$  time if the cost for every edge is equal to each other. Therefore, the representative tree for a DAG can be constructed in linear time.

By traversing  $G_r$  in *preorder*, each node  $v$  will obtain a number  $pre(v)$ ; and by traversing  $G_r$  in *postorder*, each node  $v$  will get another number  $post(v)$ . These two numbers can be used to recognize the ancestor-descendant relationships of all  $G_r$ 's nodes as discussed in Section 2.

In a  $G_r$  (for some  $G$ ), a node  $v$  can be considered as a representation of the subtree rooted at  $v$ , denoted  $T_{sub}(v)$ ; and the pair  $(pre, post)$  associated with  $v$  can be considered as a pointer to  $v$ , and thus to  $T_{sub}(v)$ . (In practice, we can associate a pointer with such a pair to point to the corresponding node in  $G_r$ .) In the following, what we want is to construct a pair sequence:  $(pre_1, post_1), \dots, (pre_k, post_k)$  for each node  $v$  in  $G$ , representing the union of the subtrees (in  $G_r$ ) rooted respectively at  $(pre_j, post_j)$  ( $j = 1, \dots, k$ ), which contains all the descendants of  $v$ . In this way, the space overhead for storing the descendants of a node is dramatically reduced. Later we will show that a pair sequence contains at most  $O(b)$  pairs, where  $b$  is the breadth of  $G$ .

**Example 2.** The representative tree  $G_r$  of the DAG  $G$  shown in Fig. 2(a) can be labeled as shown in Fig. 3(a). Then, each of the generated pairs can be considered as a representation of some subtree in  $G_r$ . For instance, pair (3, 3) represents the subtree rooted at  $c$  in Fig. 3(a).

If we can construct, for each node  $v$ , a pair sequence as shown in Fig. 3(b), where it is stored as a link list, the descendants of the nodes can be represented in an economical way. Let  $L = (pre_1, post_1), \dots, (pre_k, post_k)$  be a pair sequence and each  $(pre_i, post_i)$  is a pair labeling  $v_i$  ( $i = 1, \dots, k$ ). Then,  $L$  corresponds to the union of the subtrees  $T_{sub}(v_1), \dots,$  and  $T_{sub}(v_k)$ . For example, the pair sequence (4, 1)(5, 2)(6, 4)(8, 6) associated with  $d$  in Fig. 3(b) represents a union of 4 subtrees:  $T_{sub}(e), T_{sub}(f), T_{sub}(g)$  and  $T_{sub}(d)$ , which contains all the descendants of  $d$  in  $G$ .  $\square$

The question is how to construct such a pair sequence for each node  $v$  so that it corresponds to a union of subtrees in  $G_r$ , which contains all the descendants of  $v$  in  $G$ .

First, we notice that by labeling  $G_r$ , each node in  $G = (V, E)$  will be initially associated with a pair

as illustrated in Fig. 4. That is, if a node  $v$  is labeled with  $(pre, post)$  in  $G_r$ , it will be initially labeled with the same pair  $(pre, post)$  in  $G$ .

Fig. 4. Graph labeling

Fig. 5. Link lists associated with nodes in  $G$

Fig. 3. Tree labeling and illustration for transitive closure representation

To compute the pair sequence for each node, we sort the nodes of  $G$  topologically, i.e.,  $(v_i, v_j) \in E$  implies that  $v_j$  appears before  $v_i$  in the sequence of the nodes. The pairs to be generated for a node  $v$  are simply stored in a link list  $A_v$ . Initially, each  $A_v$  contains only one pair produced by labeling  $G_r$ .

We scan the topological sequence of the nodes from the beginning to the end and at each step we do the following:

Let  $v$  be the node being considered. Let  $v_1, \dots, v_k$  be the children of  $v$ . Merge  $A_v$  with each  $A_{v_i}$  for the child node  $v_i$  ( $i = 1, \dots, k$ ) as follows. Assume  $A_v = p_1 \rightarrow p_2 \rightarrow \dots \rightarrow p_g$  and  $A_{v_i} = q_1 \rightarrow q_2 \rightarrow \dots \rightarrow q_h$ , as shown in Fig. 5. Assume that both  $A_v$  and  $A_{v_i}$  are increasingly ordered. (We say a pair  $p$  is larger than another pair  $p'$ , denoted  $p > p'$  if  $p.pre > p'.pre$  and  $p.post > p'.post$ .)

We step through both  $A_v$  and  $A_{v_i}$  from left to right. Let  $p_i$  and  $q_j$  be the pairs encountered. We'll make the following checkings.

- (1) If  $p_i.pre > q_j.pre$  and  $p_i.post > q_j.post$ , insert  $q_j$  into  $A_v$  after  $p_{i-1}$  and before  $p_i$  and move to  $q_{j+1}$ .
- (2) If  $p_i.pre > q_j.pre$  and  $p_i.post < q_j.post$ , remove  $p_i$  from  $A_v$  and move to  $p_{i+1}$ . (\* $p_i$  is subsumed by  $q_j$ .\*)
- (3) If  $p_i.pre < q_j.pre$  and  $p_i.post > q_j.post$ , ignore  $q_j$  and move to  $q_{j+1}$ . (\* $q_j$  is subsumed by  $p_i$ ; but it should not be removed from  $A_{v_i}$ .\*)
- (4) If  $p_i.pre < q_j.pre$  and  $p_i.post < q_j.post$ , ignore  $p_i$  and move to  $p_{i+1}$ .
- (5) If  $p_i = p_j'$  and  $q_i = q_j'$ , ignore both  $(p_i, q_i)$  and  $(p_j', q_j')$ , and move to  $(p_{i+1}, q_{i+1})$  and  $(p_{j+1}', q_{j+1}')$ , respectively.

In terms of the above discussion, we have the following algorithm to merge two pair sequences together.

**Algorithm** *pair-sequence-merge*( $A_1, A_2$ )

Input:  $A_1$  and  $A_2$  - two link lists associated with  $v_1$  and  $v_2$ .

Output:  $A$  - modified  $A_1$ , containing all the pairs in  $A_1$  and  $A_2$  with all the subsumed pairs removed.

**begin**

1  $p \leftarrow first\_element(A_1)$ ;

```

2   $q \leftarrow \text{first-element}(A_2)$ ;
3  while  $p \neq \text{nil}$  do{
4    while  $q \neq \text{nil}$  do{
5      if  $(p.\text{pre} > q.\text{pre} \wedge p.\text{post} > q.\text{post})$  then
6        {insert  $q$  into  $A_1$  before  $p$ ;
7          $q \leftarrow \text{next}(q)$ ;} (* $\text{next}(q)$  represents the pair next to  $q$  in  $A_2$ .*)
8      else if  $(p.\text{pre} > q.\text{pre} \wedge p.\text{post} < q.\text{post})$  then
9        { $p' \leftarrow p$ ; (* $p$  is subsumed by  $q$ ; remove  $p$  from  $A_1$ .*)
10         remove  $p$  from  $A_1$ ;
11          $p \leftarrow \text{next}(p')$ ;} (* $\text{next}(p')$  represents the pair next to  $p'$  in
12          $A_1$ .*)
13      else if  $(p.\text{pre} < q.\text{pre} \wedge p.\text{post} > q.\text{post})$  then
14        { $q \leftarrow \text{next}(q)$ ;} (* $q$  is subsumed by  $p$ ; move to the
15         next element of  $q$ .*)
16      else if  $(p.\text{pre} < q.\text{pre} \wedge p.\text{post} < q.\text{post})$  then
17        { $p \leftarrow \text{next}(p)$ ;}
18      else if  $(p.\text{pre} = q.\text{pre} \wedge p.\text{post} = q.\text{post})$ 
19        then { $p \leftarrow \text{next}(p)$ ;  $q \leftarrow \text{next}(q)$ ;}
20    }
21  }
22  if  $p = \text{nil} \wedge q \neq \text{nil}$  then {attach the rest of  $A_2$  to the end of  $A_1$ ;}
23  end

```

The following example helps for illustration.

**Example 3.** Assume that  $A_1 = (7, 7)(11, 8)$  and  $A_2 = (4, 3)(8, 5)(10, 11)$ . Then,  $A = \text{pair-sequence-merge}(A_1, A_2) = (4, 3)(7, 7)(10, 11)$ . Fig. 6 shows the entire merging process.

Fig. 6. An entire merging process

Fig. 7. Illustration of merging two pair sequences

In each step, the  $A_1$ -pair pointed by  $p$  and the  $A_2$ -pair pointed by  $q$  are compared. In the first step,  $(7, 7)$  in  $A_1$  will be checked against  $(4, 3)$  in  $A_2$  (see Fig. 6(a)). Since  $(4, 3)$  is smaller than  $(7, 7)$ , it will be inserted into  $A_1$  before  $(7, 7)$  (see Fig. 6(b)). In the second step,  $(7, 7)$  in  $A_1$  will be checked against  $(8, 5)$  in  $A_2$ . Since  $(8, 5)$  is subsumed by  $(7, 7)$ , we move to  $(10, 11)$  in  $A_2$  (see Fig. 6(c)). In the third step,  $(7, 7)$  is smaller than  $(10, 11)$  and we move to  $(11, 8)$  in  $A_1$  (see Fig. 6(d)). In the fourth step,  $(11, 8)$  in  $A_1$  is checked against  $(10, 11)$  in  $A_2$ . Since  $(11, 8)$  is subsumed by  $(10, 11)$ , it will be removed from  $A_1$  and  $p$  becomes  $\text{nil}$  (see Fig. 6(e)). In this case,  $(10, 11)$  will be attached to  $A_1$  (see line 18 of Algorithm *pair-sequence-merge*()), forming the result  $A = (4, 3)(7, 7)(10, 11)$  (see Fig. 6(e)). Fig. 7 is a pictorial illustration of the result of merging  $A_1$  and  $A_2$ .

Along the topological order of a graph, we can generate the pair sequences for all the nodes, which computes the transitive closure of the graph using  $O(e \cdot b)$  time.
